

EU Refining Study 2020-2030

Dieter Sinnen
Former RTSG Chair

10th CONCAWE Symposium
25th-26th February 2013

Study facilitated by RTSG (Refinery Technology Support Group)

LP model used, as for earlier refining studies

- ▶ Nine regions represent EU27 + Norway & Switzerland
 - ▶ Each region is represented by a composite refinery
 - ▶ Each composite refinery has combined capacities of all refineries & petrochemical units in the region
- ▶ The quality of the crude processed in the EU is represented by a mix of five model crudes reflecting the EU overall crude quality
- ▶ Product imports and exports allowed:
 - ▶ Diesel, heating oil and jet fuel imports
 - ▶ Gasoline exports
- ▶ Unit yields are crude-dependent in most cases
- ▶ The model is Mass, Energy, Carbon, Sulphur & Hydrogen balanced

Product Qualities

BASE CASE 2008

Fuels Quality Directive (FQD)

2009: Sulphur-free road fuels (<10ppm S)
Diesel PAH content <8 wt%

Sulphur in Liquid Fuels Directive (SLFD):

Inland Waterway Gasoil 2011: ∇ from 1000 to 10ppm S

Marine Fuels

2010: global cap ∇ from 4.5 to 3.5% S

2010: SECA ∇ from 1.5 to 1.0% S

2015: SECA ∇ from 1.0 to 0.1% S

2020: global cap ∇ from 3.5 to 0.5% S

2020: Ferries ∇ from 1.5 to 0.5% S*

* The modelling assumed 0.1% S for ferries in 2020, a more severe reduction than that required by the SLFD

Demand (including biofuels):

- ▶ Declining total demand
- ▶ Erosion of demand for heavy fuels
- ▶ Growth of light products demand
- ▶ Increasing demand for jet fuel
- ▶ Demand for gasoline drops by 36% from 2010 to 2030

JEC "Fleet & Fuels" model:

- ▶ Source for road diesel and gasoline demand
- ▶ Evaluated scenarios for new vehicle fleet to meet the 2020/2030 target of 95/75 gCO₂/km
- ▶ Share of gasoline in conventional car fleet declines from 63% in 2010 to 50% in 2030
- ▶ Growing share of alternative fuel vehicles:
 - ▶ 10% of car sales in 2020 (6% of fleet)
 - ▶ 15% of car sales in 2030 (12% of fleet)

concawe Refined Middle Distillate demand (2005 to 2030)

Refined MD demand excludes biofuels but includes distillates imports

Positive factors for refined distillates:

- ▶ Aviation fuel ↗ by 28%
- ▶ Distillate marine fuel ↗ by 280%

Negative factors for refined distillates:

- ▶ Road diesel ↘ by 8%
- ▶ Non-road diesel ↘ by 27%
- ▶ Heating oil ↘ by 39%

The net effect from 2005 to 2030:

- ▶ Refined middle distillates demand ↘ by 11%
- ▶ Overall refined products demand ↘ by more than double this rate (23%)
- ▶ Share of distillates in total refined products demand ↗ from 49% to 60%

EU Crude supply (based on Wood Mackenzie data)

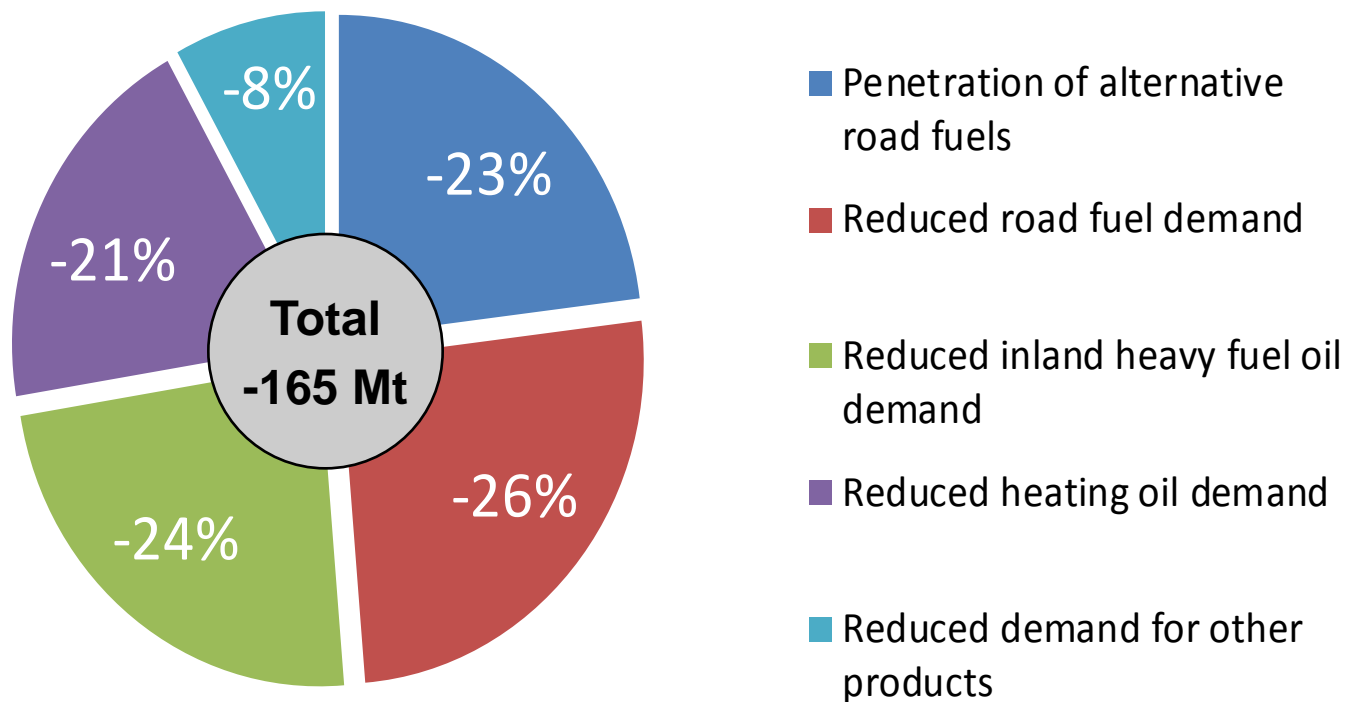

- ▶ Sources of supply for Europe will change
 - ▶ Declining light, sweet North Sea crude production
 - ▶ Replaced by other regions such as West Africa and Caspian basin
- ▶ Average quality of the EU crude slate not significantly affected

Imports/Exports (based on IEA data for 2008)

- ▶ 35 Mt/a imports of middle distillates
 - ▶ 10 Mt/a diesel, 10 Mt/a heating oil, 15 Mt/a of jet fuel.
- ▶ 43 Mt/a exports of gasoline
 - ▶ 22 Mt/a of the gasoline exports for the USA.

Factors contributing to fall in EU refined products demand 2005-2030 (%)

Note: Refined products demand excludes biofuels and gasoline exports but includes distillates imports

Process unit capacity utilisation

- ▶ Declining demand for refined products results in a substantial drop in throughput
 - ▶ 710 Mt of crude oil and feedstocks processed in 2008, falling to 600 Mt in 2030
 - ▶ Equivalent to the combined capacity of the 6 largest EU refineries (or the 30 smallest)
- ▶ CDU utilisation rate falls sharply from 86% in 2008 to 75% in 2030
- ▶ Contrasting trends for other process units
 - ▶ Severe under-utilisation of Crude Distillation units (CDU), Reforming (REF) and Fluid Catalytic Cracking (FCC) units.
 - ▶ Big increases in throughput of conversion units: Distillate Hydrocracking (DHC), Coking (COK), Residue Desulphurisation (RES HDS) and Hydrogen production (H2U)
 - ▶ These throughput increases far exceed the current or projected unit capacities
 - ▶ Major capacity adaptations would be needed to meet future demand and quality requirements

Reproduction permitted with due acknowledgement

Note: Refined products production excludes biofuels but includes gasoline exports

- ▶ Steady increase of the middle distillate (MD) to gasoline (G) production ratio
- ▶ Mostly due to the fall in gasoline demand, as MD demand remains fairly constant
- ▶ Upward trend in MD/G production ratio is not as steep as the MD/G demand ratio
- ▶ Relatively modest shift in MD/G production ratio results from optimistic assumptions:
 - ▶ EU distillate imports and gasoline exports remain constant through to 2030
 - ▶ A secure supply exists for middle distillate imports
 - ▶ Gasoline export markets are able to absorb such high volumes, allowing EU refineries to maintain a relatively high level of gasoline production
- ▶ Real picture could be worse, requiring bigger cutbacks in gasoline production and more investment in new plant capacity for distillate production

Reproduction permitted with due acknowledgement

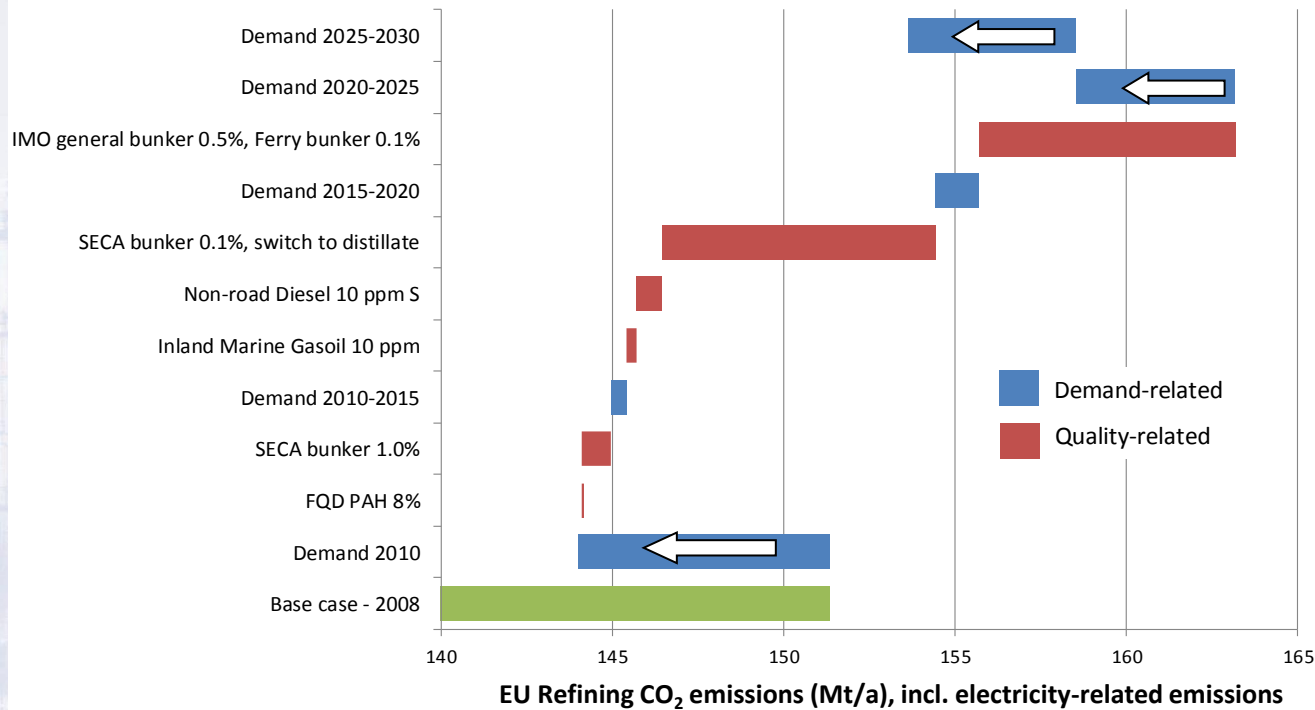

- ▶ About **\$30 billion₂₀₁₁** being spent in announced refining capacity projects in 2009-2015
 - ▶ A major contribution to meeting future requirements
- ▶ But..... the announced projects are not sufficient to meet the marine fuel sulphur reduction to 0.5% in 2020
- ▶ Additional capacities needed, on top of the \$30 billion known projects:
 - ▶ 13 Mt/a in Coking units
 - ▶ 3 Mt/a in Residue HDS units
 - ▶ 6 Mt/a in Distillate HDS units
 - ▶ 0.9 Mt/a in Hydrogen production units

Raises overall investment requirement to **\$51 billion₂₀₁₁** in 2009-2020 period

Reproduction permitted with due acknowledgement

Note: Refinery energy efficiency is assumed to remain unchanged

- ▶ Increase in CO₂ emissions due to more intensive processing:
 - ▶ Higher throughput in CO₂-intensive units (hydrocracking, desulphurisation, coking)
 - ▶ Increased production of hydrogen for cracking and desulphurisation reactions
- ▶ Refinery CO₂ emissions per tonne throughput reach 255 kg/t in 2030 (214 kg/t in 2008)
- ▶ Hydrogen production contributes 22% of refinery CO₂ by 2020 (12% in 2008)
- ▶ Refinery CO₂ emissions increase by 12 Mt from 2008 to 2020

Sensitivities around 2020 base assumptions:

- ▶ Refined road diesel to gasoline (D/G) demand ratio
- ▶ On-board scrubbers to meet IMO emissions reductions
- ▶ Gasoline octane qualities
- ▶ Jet fuel sulphur reduction
- ▶ Road diesel poly-aromatics reduction
- ▶ Heating oil sulphur reduction
- ▶ Inland heavy fuel oil sulphur reduction
- ▶ Reduced gasoline exports

Sensitivities around 2030 base assumptions:

- ▶ High biofuels
- ▶ Refinery energy efficiency improvement

Alternative base case:

- ▶ Limited refining investment in 2020

Assumptions:

The share of diesel cars in 2020 new car sales was varied between 10% and 90% (vs. 50% in base case)

- ▶ Resulting Diesel/Gasoline demand ratio varies between 1.7 and 5.0
- ▶ Road fuel energy demand kept constant
- ▶ Target of 95gCO₂/km always met

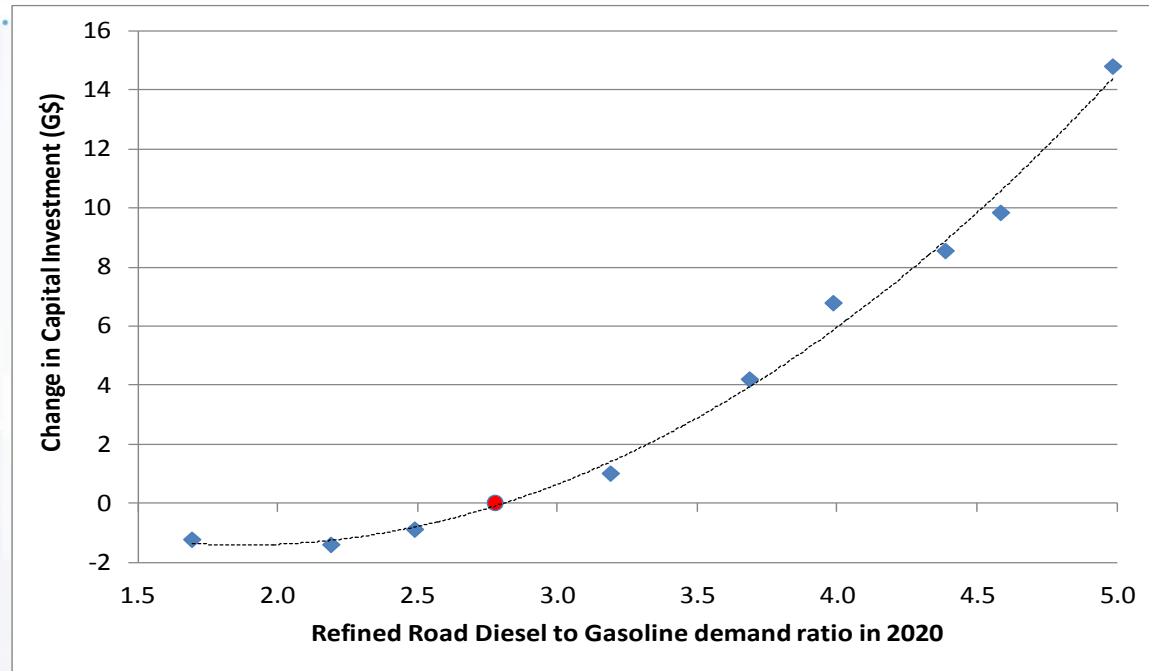

Results:

- ▶ Raising diesel production requires increased DHC (Distillate Hydrocracker) throughput and additional hydrogen
- ▶ Lowering gasoline production requires reduced throughput in FCC (Fluid Catalytic Cracker) and REF (Catalytic Reforming) units.
- ▶ FCC unit operation is modified to maximise the yield of distillate components

Reproduction permitted with due acknowledgement

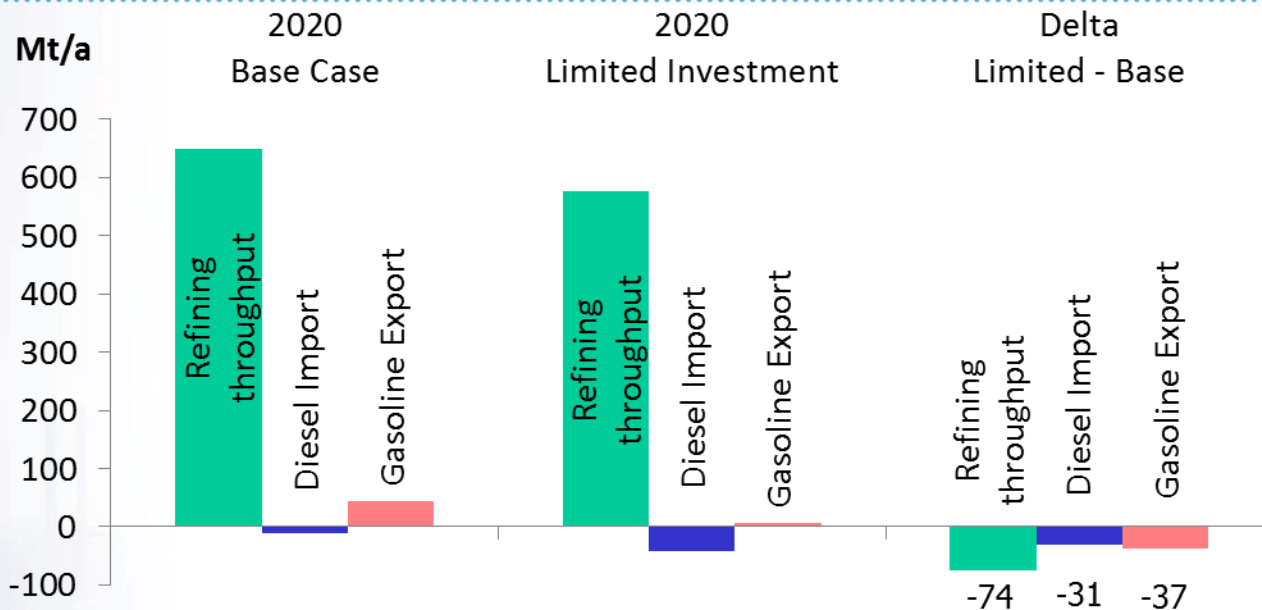

- ▶ The maximum D/G case requires almost \$15 billion more investment than the \$51 billion in the 2020 base case
 - ▶ Mostly made up of additional DHC (Distillate Hydrocracker), HDS (Hydrodesulphurisation) and H2U (hydrogen unit) capacity
- ▶ The minimum D/G cases reduce investment by up to \$1.4 billion compared to the 2020 base case, mainly through reduced hydrogen unit investments
 - ▶ DHC investments cannot be reduced below the 2020 base case level because this level corresponds to the already committed investments in the 2009-2015 period

Reproduction permitted
with due acknowledgement

- ▶ **What would happen in 2020 if there are no additional investments beyond the known 2009-2015 projects, all other things remaining equal?**
- ▶ Available processing capacity unable to remove enough sulphur to meet the 0.5% limit in marine fuels
- ▶ No export market for high sulphur Heavy Fuel Oil
- ▶ Refining throughput cut back by 11% (74 Mt) to reduce total sulphur entering the system
- ▶ Product imports/exports must adapt to satisfy demand and quality requirements
 - ▶ Diesel imports: ↗ by 310% (31 Mt)
 - ▶ Gasoline exports: ↘ by 86% (37 Mt)

Reproduction permitted with due acknowledgement

- ▶ CDU throughput reduction and import/export adjustments affect other units:
 - ▶ Reduced utilisation rates in REF (Reforming) and DHDS (Distillate Hydrodesulphurisation) units due to reduced CDU production of naphtha and gasoil
 - ▶ FCC utilisation rate is doubly impacted by:
 - ▶ Reduced feed availability from CDU
 - ▶ Feed switch to DHC (Distillate Hydrocracking) to maximise diesel production and minimise the import of diesel
- ▶ This scenario would present severe challenges for the EU refining industry

Reproduction permitted with due acknowledgement

- ▶ The announced projects from 2009 to 2015 are a major contribution to meeting future refined product requirements
 - ▶ Committed capital expenditure estimated at \$30 billion₂₀₁₁ (€21 billion₂₀₁₁)
- ▶ Additional capital expenditure of \$21 billion₂₀₁₁ (€15 billion₂₀₁₁) would be required to meet the 0.5% sulphur limit on marine fuels by 2020
- ▶ The long-term demand in refined products will continue to decline
 - ▶ Refiners could have difficulty justifying the additional expenditure
 - ▶ Without additional capital expenditures the 2020 market demand would need to be satisfied by substantial increases in diesel imports and a further reduction in refinery utilisation rates
- ▶ CO₂ emissions from EU refining are expected to increase by 2020
- ▶ Declining demand post-2020 will reduce refining CO₂ emissions to a level in 2030 that is, at best, close to that of 2010

Thank you for your attention!
